Abstract
The increasing private sectors are focusing employment of eco friendly renewable/green power technologies like PV Cells, Fuel Cells, Wind turbine to meet the growing power demand. This paper presents the analysis and operation of PV system using Multilevel DC to DC Boost Converter Topology. The DC to DC Multilevel Boost converter is based on one inductor, one switch, 2N-1 diodes and 2N-1 capacitors, for an Nx converters, it is a boost converter able to control and maintain the same voltage in all the N output levels and able to control the input current. The proposed model and their performance are evaluated for varying loads in MATLAB/Simulink environment.

Keywords – PV array, Multilevel boost converter, Matlab, simulink

1. Introduction
Increased energy utilization and global pollution awareness have made green/renewable power more and more important for stand alone as well as distributed generation. Wind turbines, Photovoltaic and Fuel Cells are different types of green power technologies. Photovoltaic systems have been extensively employed for large power generation around the whole world in recent decades. The conversion of solar energy into electric energy is performed by means of photovoltaic cells.

In order to adapt the output Voltage of the energy supplies/storage systems the medium voltage level, boosting of the DC voltage is required. For large voltage step-up ratios this task is advantageously performed by DC-DC converters[1]. Since the PV array delivers Dc power, it must be inverted to AC and stepped-up to be able to use for household applications as well as for distributed generation and output voltage is regulated desired level. Therefore a suitable Power electronic interface is required between PV array and load, with the capabilities of balance output voltage.

Above task can be achieved by connecting a DC-DC converter with voltage gain to the PV array. The proposed model of renewable energy fed Multilevel Boost converter using Matlab/simulink is given Figure(1).

PROPOSED MATLAB /SIMULINK MODEL OF PV ARRAY FED MULTILEVL BOOST CONVERTER

Figure1 .Proposed Multilevel Boost Converter for PV array Application.
Several topologies of switched mode DC-DC converter followed by dc source are proposed and compared based on their performance. A switch mode DC-DC converter is preferred to limit the size and cost of the system. A current fed DC-DC converter is preferred over the voltage fed DC-DC converter as the former requires reduced input filtering. A push pull DC-DC converter is selected with voltage gain to reduce the switches conduction losses. However, its use is restricted to own ad medium power applications. Full bridge topology is preferred for high power applications as push-pull topologies have a serious problem of centre tap termination, which tends to cause saturation of the transformer at high power levels, though a full bridge requires more switches of half rating, which is more economical & efficient.

All these topologies discussed above, uses multiple stage conversion to deal with the above mentioned challenges, which results in large component count, therefore poor reliability, additional cost, and low efficiency. In addition to this, energy storage devices such as battery and ultra capacitors are also needed at various stages either to supply auxiliaries or to improve the slow transient’s response of the PV array.

2. MODELLING OF PV ARRAY

The building blocks of PV array are the solar cell, which is basically a p-n junction that directly converts light energy into electricity, it has an equivalent circuit as shown below in figure.

![Figure 2: Electrical Circuit of PV Module](image)

The current sourceIpv represents the cell photo current, Rs and Rs are used to represent the intrinsic series and shunt resistance of the cell respectively. Usually the value of Rs is very large and that of Rs is very small, hence they may be neglected to simplify the analysis. PV cells are grouped in larger units called PV modules which are further interconnected in series-parallel configuration to form PV arrays [2]. The PV mathematical model used to simplify our PV array is represented by the equation.

\[ I = n_p I_{ph} - n_p I_{rs} \left[ \exp\left( \frac{qV}{KT A_n} \right) - 1 \right] \] (1)

Where \( I \) is the PV array output current, \( V \) is the PV array output Voltage, \( n_s \) is the number of cells in series and \( n_p \) is the number of cells in parallel, \( q \) is the charge of an electron, \( k \) is the Boltzmann constant, \( A \) is the p-n junction ideality factor, \( T \) is the cell temperature (K), \( I_{rs} \) is the cell reverse saturation current. The factor \( A \) in equation determines the cell deviation from the ideal p-n junction characteristics it ranges between 1-5 but for our case \( A = 2.46 \) [3].

The cell reverse saturation current \( I_{rs} \) varies with temperature according to the following equation:

\[ I_{rs} = I_{rr} \left( \frac{T}{T_r} \right)^3 \exp\left[ \frac{(qEG)/(KA)} \right] \left( \frac{1}{T_r} - \frac{1}{T} \right) \] (2)

The temperature dependence of the energy gap of the semiconductor is given by

\[ E_G = E_G(0) - \left( \frac{qT^2}{T + \beta} \right) \] (3)

The photo current \( I_{ph} \) depends upon on the solar radiation and cell temperature as follows:

\[ I_{ph} = (I_{src} + K_i(T-T_r))S \left( \frac{100}{100} \right) \] (4)

The power can be calculated as

\[ P = VI = n_p I_{ph} V \left[ \left( \frac{qV}{KT A_n} \right) - 1 \right] \] (5)

3. MODELLING OF DC-DC MULTILEVEL BOOST CONVERTER

Figure 7. shows the multilevel boost converter “MBC”. An Nx MBC is based on one driven switch 2N-1 diodes and 2N-1 capacitors, the number of levels can be extended by adding capacitors and diodes and the main circuit does not need to be modified[4].

The lower part of the converter is the conventional Boost Converter, then the voltage gain also holds for the well know boost converter equations. The difference between the multilevel boost converter and the conventional one is that in the multilevel boost converter the output is Vc ,times N, where N+1 is the converter’s number of levels take into account the zero level. This behavior is achieved thanks to the voltage multiplier in the output of the boost converter which is driven by the switch in the converter.
3.1 TURN ON AND TURN OFF STATES

The multilevel principle of this converter will be explained through a $4x(5$ levels) DC-DC boost converter. To explain the multilevel principle, assume that the switch $(s)$ is switching with a duty ratio $(d)$ of 0.5. During the switch-on state, the inductor is connected to $V_{in}$ voltage. Figure 8a. If $C_6$ voltage is smaller than $C_7$ voltage then $C_7$ clamps $C_6$ voltage through $D_6$ and the switch $S$. Figure 8b. At the same time if the voltage across $C_4 + C_6$ is smaller than the voltage across $C_5 + C_7$, then $C_5$ and $C_7$ clamps the voltage across $C_4$ and $C_6$ through $D_4$ and $S$. Figure 6c. In a similar $C_3$ and $C_7$ clamps the voltage across $C_2$, $C_4$ and $C_6$ in Figure d.

When the switch turns off, the inductor current closes $D_7$, and switches all diodes. During the switch Off state, the inductor current closes $D_7$ charging $C_7$. Figure 9a. When $D_7$ closes, $C_6$ and the voltage in $V_{in}$ plus the inductor’s voltage clamp the voltage across $C_5$ and $C_7$ through $D_5$. Figure 9b. Similarly, the voltage across $C_3$, $C_5$ and $C_7$ through $D_3$. Finally the voltage across $C_1$, $C_5$, $C_3$ and $C_7$. Is clamped by $C_2$, $C_4$, $C_6$, $V_{in}$ and the inductor voltage in Figure 9c. It is noteworthy that $D_1$, $D_3$, $D_5$ and $D_7$ switch in a synchronously way, complemented with $D_2$, $D_4$, $D_6$ and $S$.

The transfer function of Conventional Boost converter is:

\[ V_{out} = \frac{V_g}{1-D} \]

But in the Multilevel Converter the transfer function is:

\[ V_{out} = \frac{V_g \times N}{1-D} \]

It is shown from last two equations that the Multilevel Boost converter has a big conversion ratio without extreme duty cycle depending on the level of it[5].

4. SIMULATION RESULTS

The simulink model of the Photovoltaic array fed Multilevel Boost Converter is modeled in Figure 1 using Matlab/simulink environment. The simulation work is carried out for a triangular waveform of 10KHz switching frequency for the Multilevel Boost converter its switching pattern model is shown in figure 9.
The waveform of switching pulse generation for Mosfet is shown in Figure.10 and Figure.11.

### 5. CONCLUSION

The open circuit P-V, P-I and I-V curves we obtained from the simulation of the PV array designed in MATLAB environment explains in detail its dependence on the irradiation levels and temperatures. The entire energy conversion system has been designed in MATLAB-SIMULINK environment. The various values of the voltage...
and current obtained have been plotted in the open circuit I-V curves of the Photovoltaic array at insolation levels of 100mW/cm² and 80mW/cm². The Voltage and current values lie on the curve showing that the coupling of the PV array with the Multilevel Boost Converter is proper[6]. However the performance of the photovoltaic device depends on the spectral distribution of the solar radiation.
