Abstract
Mathematical models for the determination of the uplift resistance of gas pipelines network system have been developed. The computer simulation of the mathematical models is the bane of this work. The paramount parameters in view to be determined by computer simulated algorithms are optimal wall thickness, the restoring moment, pipe deflection and pipe support spacing for a laid pipeline to avoid buckling of the pipeline subject to the different loading conditions. At nominal pipe wall thickness of 11cm, the simulated optimal wall thickness is 17cm. The simulation results confirmed the deflection of the pipe as -2.698m, the restoring force as -3.33x10^{17}N. Subject to these findings, three pipe supports are required to bear restoring the load of 1.11x10^{17}N at each support.

Keywords: Uplift Resistance; Earth Mass Centroid; Pipe Thickness; Maximum Deflection; Internal Fluid Pressure; External Loads; Support Reaction; Buckling Load.

1. Introduction
Gas pipelines assets and facilities are expensive capital-intensive production items designed to have a long service life. Failure of these vital production assets might have serious economic and environmental implications. There are published works on uplift mechanisms of buried pipeline caused by creep, earth movement, inadvertently resulting in infilling of soil at the base of the pipe [1, 2, 3, 4, 5]. This situation will result in pressure build-up at the base of the pipe, leading to gradual drift of the pipe to the earth surface. The worst case situation is the buckling of the pipe.

Oil and gas pipeline mechanical design concepts based on ANSI/ASME set of standard codes adequately specified design equations for pipe wall thickness, flow velocity, compressors, valves, fittings and flanges design, pipe support spacing, flow density, and pipe internal diameter. The applicable set of standard codes are ANSI/ASME B31, 3, B31.4, B31.8, and API RP14C [6,7,8,9].

The easiest, safest and the most efficient and economical means of transportation or transmission of fluid be it liquid or gas is through interconnected pipes generally referred to as pipeline network system. In the gas transmission system, the pipeline is in three subcategories namely: the gathering pipeline (field pipeline), the
main trunk line and the service or distribution line. By virtue of the terrain transversed by the pipeline, weight of
the pipes and that of the fluid being conducted, the pipeline might be subject to diverse stresses and subsequently
buckling. This necessitates the need for a model formulation to determine the safe pipe wall thickness, the uplift
resistance of the pipe that will prompt accurate pipe support spacing on the basis of deflection of the pipe.
Computer simulation of the developed models has been incorporated into this work to enable the determination
of the controlling parameters for the uplift resistance. This approach would culminate in improved design, higher
transmission efficiency and lesser cost of installation of gas pipeline assets and facilities. The geometric
representation of the pipeline system for stresses and uplift resistance computations are as in Figures 1 to 5.

2. Purpose and Significance
Uplift mechanisms of a buried pipe or the prevailing conditions militating for the upward drift of a buried pipe
had been reviewed. Oil and gas pipelines mechanical design concepts were reviewed in all its details. This work
strongly rooted on the formulation of mathematical models for the uplift resistance of laid buried pipeline, is to
enable the determination of optimal pipe wall thickness, support reactions, and pipe deflection. The pipeline
irrespective of the length is imagined as supported at the ends. It is believed if the pipe deflection is known to a
measure of accuracy pipe supports can be installed along the pipeline to annul the deflection to avoid
catastrophic failure due to buckling. The computer simulation of mathematical models would enable the
determination of those paramount parameters such as supports reactions, optimum wall thickness, bending
moment, pipe deflection and support placement by a computational approach. This way our future oil and gas
pipelines would meet the design and operation standard required for optimal performance.

3. Mathematical Models for Computer Simulation
The geometric representation of the forces and stresses acting on the system are as presented in Figures 1 to
5. Circumferential stress on the structure is expressed as:

\[
\sigma_1 = \frac{Pd_1}{2t}
\]  

(1)

Longitudinal stress is given as:

\[
\sigma_2 = \frac{Pd_1}{4t}
\]  

(2)

Pipe mean diameter

\[
d_m = \frac{d_1 + d_1 + t}{2} = d_1 + t/2
\]  

(3)

The expression for the radial stress goes thus;

\[
\sigma_3 = \frac{Pd_1 - P_{\text{ext}} (d_1 + t)}{d_1 + t/2}
\]  

(4)

Where:
P—average stream pressure (N/m²)
\(\sigma_1\)—hoop stress or circumferential stress (N/m²)
L—pipe length (m)
Mathematical Theory and Modeling
ISSN 2224-5804 (Paper)    ISSN 2225-0522 (Online)
Vol.8, No.1, 2018

t, \bar{t} — pipe thickness (m)
d_1 — pipe internal diameter (m)
The resultant external loads on the structure is expressed as:

$$P_{ext} = P_{atm} + P_{earth} + P_c + P_w$$

$$P_{atm} = 1 \text{bar}$$

$$P_{earth} = \rho_s g \bar{h}$$

$$P_w = \varphi P_g \text{ at } (33^\circ C)$$

If the pipe is encased in a concrete of thickness $t_1$, the load intensity is expressed as,

$$P_c = \frac{F_c}{A_c} = \frac{m_c \bar{g}}{A_c} = \frac{\rho_c V_c \bar{g}}{A_c}$$

$$= \frac{\rho_c \bar{t} g (d_2 + d_1)}{2d_1}$$

$$A_c = \pi d_2 \bar{L}$$

$$V_c = \frac{\pi (d_2^2 - d_1^2) \bar{L}}{4} = \frac{\pi (d_2 + d_1)(d_2 - d_1) \bar{L}}{4}$$

$$d_2 - d_1 = 2t$$

Where:

$\sigma_2$ — longitudinal stress (N/m²)
d_m — pipe mean diameter (m)
P_ext — resultant external loads on the pipe (N/m²)

$\sigma_3$ — radial stress (N/m²)
P_ext — resultant external loads on the pipe (N/m²)
P_atm — atmospheric pressure (N/m²)
P_earth — pressure due to overlying earth (N/m²)
P_c — pressure due to the weight of the concrete coating (N/m²)
P_w — pressure due to atmospheric water vapor water (N/m²)
F_c — Force exerted by the casing (N)
m_c — mass of the concrete casing (kg)
t_1 — casing thickness (m)
$\rho_c$ — density of casing material (kg/m3)
Subject to the tri-axial stress condition, the maximum shear stress is the greatest of the three values.

\[ \tau_{1\max} = \left| \frac{\sigma_1 - \sigma_2}{2} \right| \text{ or } \left| \frac{\sigma_2 - \sigma_3}{2} \right| \text{ or } \left| \frac{\sigma_3 - \sigma_1}{2} \right| \]

\[ \therefore \quad \tau_{1\max} = \left| \frac{\sigma_3 - \sigma_1}{2} \right| \]  

Under uni-axial stress condition, \( \sigma_2, \sigma_3 = 0 \)

\[ \tau_{2\max} = \frac{\sigma_1}{2} \]  

Temperature stress in the system is expressed as:

\[ \sigma_T = E\varepsilon = E \frac{\Delta L}{L} = E \frac{\alpha L \Delta T}{L} = E \alpha \Delta T \]  

On the basis of these analyses the overall induced maximum shear stress in the pipe can be expressed as:

\[ \tau_{\max} = \tau_{1\max} - \tau_{2\max} = \frac{\sigma_1 - \sigma_2}{2} - \frac{\sigma_T}{2} \]  

Applying failure (yielding) analysis known as maximum shear stress theory.

\[ \sigma_1 - \sigma_3 - \sigma_T = \frac{\sigma_{yp}}{F' S} \]  

\( \sigma_{yp} \) is the yield point of the pipe material under uni-axial tension test.

Where:

\( \sigma_3 \) -- radial stress (N/m²)
\[ \tau_{1\text{max}} - \text{maximum shear stress under tri-axial stress condition (N/m}^2) \]
\[ \tau_{\text{max}} - \text{induced maximum shear stress in the pipe (N/m}^2) \]
\[ \sigma_T - \text{temperature stress (N/m}^2) \]
\[ E - \text{poisson ratio} \]
\[ E - \text{Young’s modulus of elasticity for the pipe (N/m}^2) \]
\[ \alpha - \text{linear expansivity of the pipe material (°C)} \]
\[ \Delta T - \text{temperature difference between the pipe gas and the environment (°C)} \]
\[ \Delta L - \text{change in length of the pipe (m)} \]

\[
\begin{align*}
\frac{Pd_1}{2t} - \frac{Pd_1 - P}{d_1 + t/2} - \sigma_T &= \frac{\sigma_{\text{urt}}}{FS} \\
\bar{t}^2 &- 2P_{\text{urt}} - \sigma_T - \frac{\sigma_{\text{urt}}}{FS} \right) + t \left[ -1.5Pd_1 + 2P_{\text{urt}}d_1 - 2\sigma_Td_1 - \frac{2\sigma_{\text{urt}}}{FS} \right] + pd_1 = 0
\end{align*}
\]

\[ a = -2P_{\text{urt}} - \sigma_T = \frac{\sigma_{\text{urt}}}{FS} \]
\[ b = -1.5Pd_1 + 2P_{\text{urt}}d_1 - 2\sigma_Td_1 - \frac{\sigma_{\text{urt}}}{FS} \]
\[ c = Pd_1 \]
\[ \bar{t} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \]

\( \bar{t} \) is the design wall thickness of the pipe for safe operation with due regard to the required operating conditions.

The centroid of the earth mass above the pipe is expressed as:
\[
\bar{x} = \frac{(L - L_1) \left( h - \frac{d_2}{2} \right) \left( \frac{L - L_1}{2} \right) + L_1 \left( h - \frac{d_3}{2} \right) \frac{2L - L_1}{2}}{(L - L_1) \left( h - \frac{d_2}{2} \right) + L_1 \left( h - \frac{d_3}{2} \right)}
\]

The load components are:

(i) Pipe Weight

\[
W_p = m_p g = \rho_p V_p g = \frac{\pi L_p \rho_p g (d_1^2 - d_2^2)}{4}
\]
(ii) Concrete Weight

\[ W_c = m_c g = \rho_c V_c g = \pi L \rho_c g \left( \frac{d_1^2 - d_2^2}{4} \right) \]  

(14)

(iii) Earth Mass Weight

\[ W_e = m_e g = \rho_e V_e g = \pi \rho_e g \left[ \frac{h^2 L - \frac{d_2^2 L}{4} - \left( \frac{d_3^2 - d_2^2}{4} \right) L_1}{4} \right] \]  

\[ V_e = \pi \left[ \frac{h^2 L - \frac{d_2^2 L}{4} - \left( \frac{d_3^2 - d_2^2}{4} \right) L_1}{4} \right] \]  

Where:

- \( m_p \) — mass of pipe (Kg)
- \( m_c \) — mass of concrete (Kg)
- \( m_e \) — mass of overlying earth (Kg)
- \( m_H \) — mass of hydrocarbon constituents (Kg)
- \( m_i \) — mass fraction of the constituents (Kg)
- \( n_i \) — number of moles of the constituents
- \( M_i \) — molar mass of the constituents (Kg)
- \( R \) — average gas constant for the constituents (J/KgK)
- \( R_i \) — gas constant for the constituents (J.KgK)
- \( g \) — gravitational acceleration (m/s^2)
- \( W_p \) — weight of pipe (N)
- \( W_c \) — weight of concrete (N)
- \( W_e \) — weight of overlying earth mass (N)
- \( W_g \) — weight of pipe (N)
- \( F \) — restoring force (N)
- \( R_1, R_2 \) — reactions at the supports (N)
Applying Macaulay’s method [10], for the moment distribution along the pipeline,

\[ EI \frac{d^2 y}{dx^2} = M \]

\[ = R_1 x - W_c \left( x - \frac{L_1}{2} \right) - W_p \left( x - \frac{L}{2} \right) - W_n \left( x - \frac{L_1}{2} \right) - W_e \left[ x - \left( L - \bar{x} \right) \right] \]

\[ EI \frac{dy}{dx} = \frac{R_1 x^2}{2} - W_c \left( \frac{x^2}{2} - \frac{L_1 x}{2} \right) - \left( W_p + W_n \right) \left( \frac{x^2}{2} - \frac{L x}{2} \right) - W_e \left( \frac{x^2}{2} - \frac{L_1 x - \bar{x} x}{2} \right) + A_1 \]

\[ EI y = \frac{R_1 x^3}{6} - W_c \left( \frac{x^3}{6} - \frac{L_1 x^2}{4} \right) - \left( W_p + W_n \right) \left( \frac{x^3}{6} - \frac{L x^2}{4} \right) - W_e \left( \frac{x^3}{6} - \frac{L_1 x^2}{2} + \frac{\bar{x} x}{2} \right) + A_1 x + B_1 \]

Applying the boundary conditions when \( x = 0, y = 0 \) and when \( x = L, y = 0 \)

\[ B_1 = 0 \]

\[ A_1 = W_c \left[ \frac{L_1^2}{6} - \frac{L_1 L}{4} \right] - \frac{L^2}{12} \left[ W_p + W_n \right] + W_e \left( \frac{\bar{x} L}{2} - \frac{L^2}{3} \right) - \frac{R_1 L^2}{6} \]

The reaction \( R_1 \) and \( R_2 \) are given as,

\[ R_1 = \frac{W_c \left( \frac{2L - L_1}{2} \right) + \left( W_p + W_n \right) L/2 + W_e \bar{x}}{L} \]

\[ R_2 = (W_c + W_e + W_p + W_n) - R_1 \]

At the point of maximum deflection, \( dy/dx = 0 \), hence,

\[ x^2 \left[ \frac{R_1}{2} - \frac{W_c}{2} - \left( \frac{W_p + W_n}{2} \right) - \frac{W_e}{2} \right] - x \left[ \frac{W_c L_1}{2} + \frac{(W_p + W_n) L}{2} + W_e \left( L - \bar{x} \right) \right] + A_1 = 0 \]

\[ a_1 = \frac{R_1}{2} - \frac{W_c}{2} - \left( \frac{W_p + W_n}{2} \right) - \frac{W_e}{2} \]

\[ b_1 = \left[ \frac{W_c L_1}{2} + \frac{(W_p + W_n) L}{2} + W_e \left( L - \bar{x} \right) \right] \]

\[ c_1 = A_1 \]

\[ \bar{x} = \frac{-b_1 \pm \sqrt{b_1^2 - 4a_1 c_1}}{2a_1} \]

The maximum deflection maximum deflection is expressed as:

\[ y = \left[ \frac{R_1 \bar{C}^3}{6} - W_c \left( \frac{\bar{C}^2}{6} - \frac{L_1 \bar{C}^2}{2} \right) - \left( W_p + W_n \right) \left( \frac{\bar{C}^3}{6} - \frac{L_1 \bar{C}^2}{4} \right) - W_e \left( \frac{\bar{C}^2}{6} - \frac{L \bar{C}^2 + \bar{x} \bar{C}^2}{2} \right) + A_1 \bar{C} \right] / EI \]

The bending moment at the point of maximum deflection is given by the expression:

\[ M = R_1 \bar{C} - W_c \left( \bar{C} - \frac{L_1}{2} \right) - \left( W_p + W_n \right) \left( \bar{C} - L/2 \right) - W_e \left[ \bar{C} - \left( L - \bar{x} \right) \right] \]
The restoring force, $F$, at point of maximum deflection is given as

$$ F_y = M, \quad F = M / y $$

This is the required force to prevent buckling of the pipeline subject to the loading conditions. This force can be offered by providing additional support at point $C$ or overdesigning the pipe to be of such thickness to withstand the buckling load $F$. The buckling load $F$ is referred as the uplift resistance of the pipe.

4 Computer Simulation for the Determination of the Uplift Resistance

The programming language is MATLAB [11].

5. Model Application
The concept of uplift resistance can be applied to oil or gas pipelines network system to provide additional supports to prevent buckling of the pipeline. It is a well-known fact that oil and gas pipelines are laid over a distance of thousands of kilometers and they are expensive production assets that last for long period of time. Hence the structure should be well designed with adequate support spacing.

6 Recommendation
The simulated computational results should be applied to the physical gas pipeline at the design and installation stage. This is to enhance the service and operational life of this expensive production asset.

7 Conclusion
Computer simulation of gas pipeline uplift resistance has been developed for the determination of safe optimum
pipe wall thickness, uplift resistance, and the point of maximum pipe deflection to enable proper spacing of pipe supports. This is to avoid failure of the pipe by the reason of fatigue and bending stresses that will ultimately result in the buckling of the pipe under service conditions.
