Abstract

The importance of the estimation of a congruous discount rate for unlisted companies is due to its use in evaluation process. The cost of equity is usually defined from CAPM that does not suit for unlisted companies. In the previous paper we analyzed the accounting beta model, using CAPM beta as comparison point, identifying the stability of the model. However CAPM beta is based on the hypothesis that all the investors diversify their portfolio, while in some context most of investor do not. So the aim of this research is to pay attention on the accounting beta, that is a model suitable for unlisted companies, starting from total beta that consider the phenomenon of non-diversification. In order to reach the goal, after a literature review, we have conduct an empirical analysis to find the differences from the approach of total beta and the approach of CAPM beta.

Keywords: total beta, diversification, cost of equity, SME, CAPM beta, accounting beta, unlisted companies, Italian market

1. Introduction

This paper is a continuation of Intrisano, Palomba, Di Nallo, Calce (2017). The aim of this article is to verify the adaptability of accounting beta model, using as comparison point the total beta, that considers non-diversification. In particular we want to identify any differences respect to Intrisano, Palomba, Di Nallo, Calce (2017), in order to check stability of accounting beta among total beta.

This need born from the entrepreneurial condition of some countries. In fact as reported in Muller et al (2015) SMEs are backbone of the European economy because they represent 99% of all businesses. In particular in France, Italy, Portugal and Spain they play a fundamental role. Some research like Friend and Blume (1975), Polkovnichenko (2005), Goetzmann and Kumar (2002), Calvet, Campbell e Sodini (2007) show that investors tend to center their financial resources in few stocks, for different reasons, included the need of concentrate their resources in SME's capital. Focusing on Italy, It can be said that SMEs are very popular. The idea that SMEs are often not listed is confirmed by Pagano, Panetta, Zingales (1998), in fact they assert that the likelihood of an IPO is increasing in the company's size and the industry's market-to-book ratio. So in Italy, like in other countries where SMEs are widely diffused, the necessity of a model that consider non diversification emerges. The model mostly used to calculate cost of equity is CAPM introduced by Sharpe (1964) as a pursuance of Markowitz (1958). As already mentioned this model does not suit for unlisted companies, due to diversification problem. So some academics have focus on model built for unlisted companies. The most important model are fundamental beta and accounting beta. Fundamental beta is introduced by Beaver, Kettler, Scholes (1970) and Rosenberg, Marathe (1979). The idea is to link CAPM beta to explanatory financial data. Also Damodaran (2006) follows this setting. Accounting beta provides a linear regression between accounting measure of company and the average of the same accounting measure of related to all the listed companies of the market. Accounting beta represents a model suitable for unlisted companies and not related to CAPM beta.

In the next paragraph, we will pay attention on academic literature about total beta and accounting beta.

2. Literature review

Camp ed Eubank (1981) first introduce the total beta measure, initially identified as the beta quotient. The two authors, starting from the consideration that often even the funds present beta with R^2 not very high, condition that represent an inefficient diversification, try to identify a risk measure that also incorporates the specific risk. Beta quotient is the ratio between the beta resulting from the CAPM and the square root of the R^2 of the regression.

Next the steps for the definition of total beta.

It starts from the definition of R^2 . In the linear regression:

$$R^2 = \rho^2 \quad (1)$$

from which $R = \rho$

Correlation coefficient:

$$\rho = \frac{\text{cov}(j,m)}{\sigma_j \sigma_m} \quad (2)$$

We can explain covariance in terms of beta:

$$\beta = \frac{\text{cov}(j,m)}{\sigma_m^2} \quad (3);$$

$$\text{cov}(j,m) = \beta \sigma_m^2 \quad (4)$$

So replacing (4) in (2):

$$\rho = \frac{\beta \sigma_m^2}{\sigma_j \sigma_m} \quad (5),$$

Simplifying:

$$\rho = \frac{\beta \sigma_m}{\sigma_j} \quad (6)$$

$$\text{Remembering (1): } \frac{\beta \sigma_m}{\sigma_j} = R \quad (7)$$

Now from (7) explain σ_j :

$$\sigma_j = \frac{\beta \sigma_m}{R}$$

From which:

$$\sigma_j = \text{Beta quotient} * \sigma_m;$$

$$\frac{\sigma_j}{\sigma_m} = \text{Beta quotient}.$$

Given the expression of CAPM beta

$$\beta_m = \frac{\rho_{j,m} * \sigma_j}{\sigma_m}$$

It is possible to affirm

$$\beta_m = \text{Beta quotient} * \rho_{j,m}$$

$$\text{Beta quotient} = \frac{\beta_m}{\rho_{j,m}}$$

This concept is then taken up again by Damodaran (2006) with the definition of total beta. The main proponents of this approach are Butler and Pinkerton (2006) who try to provide empirical and academic evidence to support this risk measure. Their main purpose is not the determination of the total risk but of the specific risk, as they assume inappropriate the practice according to the benchmark for the specific risk is equal to 0%.

As in Camp, Eubank, It starts from the concept of diversification. The basic assumption to use total beta is the presence of an investor with a non-diversified portfolio. If a non-diversified buyer competes with a fully diversified buyer who uses the CAPM, according to which only systematic risk is considered, the return requested by the non-diversified investor will be higher and therefore the market will accept the investor's return with diversified portfolio. So in this case the non-diversified buyer can not be recognized all his risk and therefore It is necessary to add an additional factor, the specific risk.

There are two empirical conditions for optimal use of total beta: presence of a high R^2 ; not high beta.

Some criticisms have been made towards the total cost of equity approach, in particular by von Helfenstein

(2009), Conn (2011) and Kasper (2008). The first author expresses some perplexities regarding the statistical significance of the intermediate results necessary for the determination of total beta. It supports facts that some statistical expressions can not undergo simple arithmetic adjustments. He also has some doubts about the relationship between the two standard deviations in fact he says that a direct comparison between two or more dispersion measures is impossible. Moreover, according to the author, it does not matter which arguments are used to justify a series of equations, if those equations violate known fundamental principles. The same accusation is raised by Kasper (2008) that say that total beta breaks the financial theory. In response, Butler and Pinkerton argue that this does not happen if we refer to cases in which the specific risk is not at all considered or is considered only marginally. Lastly, Conn, who consider not significant the accusations that the total beta is not a valid substitute for the classic beta, because in the hypothetical case of a correlation coefficient equal to one the two variables converge. He is more interested in the risk premium, and in fact, in the perspective of total betam he does not consider consistent the use of the classic risk premium of the CAPM, that is coherent with the remuneration of only systematic risk.

Regarding to accounting beta, It represents a good alternative to CAPM beta for unlisted companies because It is not linked to CAPM beta, that do not consider the problem of diversification and also because the only information about unlisted company required is an accounting measure. Instead in CAPM beta price information are necessary and unlisted companies do not have these information.

Accounting beta is the result of the linear regression between an accounting measure (dependent variable) and the market average of the same accounting measure (independent variable).

Accounting beta is introduced by Ball, Brown (1969), concluding that accounting income have an explanatory power of about 40% of the changes in CAPM beta.

Beaver, Kettles, Scholes (1970) deal with this topic. They show an high degree of association between beta and accounting variables. This association is confirmed by Beaver, Manegold (1975). Ismail, Kim (1989) tell about relationship among cash flow measures and CAPM beta. However these studies concentrate on connection between accounting beta and CAPM beta, while the aim of this paper is to investigate the contact between accounting beta and total beta.

About accounting measures emerges that: net income is used by Ball, Brown (1969), Beaver, Kettles, Scholes (1970), Beaver, Manegold (1975), Kim (2004), Almisher, Kish (2000), operating income by Ball, Brown (1969), Kim (2004).

3. Data and Methodology

Data about price and accounting measures are collected from Thomson Reuters Datastream for a ten years period (2006-2015). Panel is composed by the 303 companies that was listed in Italian market in 2015.

The data and methodology used in this paper are the same of Intrisano, Palomba, Di Nallo, Calce (2017). The aim of this paper is to verify any differences with previous study. So in order to achieve the goal the following steps are necessary: reckoning of accounting beta (ROE, net income, operating income); calculation of total beta; comparison.

As reported in literature review accounting beta model involves a linear regression between accounting measure of single stock and average accounting measure of the market. We compute this beta only for companies that have n. 10 balance sheet (2006-2015) available. When a company does not have balance sheet even for a single years the accounting beta is not calculated, while the accounting measures of the previous years are used in order to calculate average of the market. Following the literature we select net income, operating income and ROE as accounting measure.

The calculation of total beta involves other two passage: computation of CAPM beta and correlation between market index (FTSE MIB) and single stock. CAPM beta are calculated for a five years period (2011-2015) with monthly observations, as in professional practice. We do not calculate all CAPM beta but only for stocks that have complete price information in the time. The next steps are the detection of pearson correlation coefficient and the computation of total beta.

As mentioned the empirical analysis is about Italian market that in 2015 was composed by 303 companies. Only 157 companies are taken in our analysis because they have complete information to calculate at the same time total beta and three measures of accounting beta.

4. Results

The first result is that the average of total beta of 157 companies is 2,12, an higher value than average CAPM beta (0,29) of Intrisano, Palomba, Di Nallo, Calce (2017). So because total beta includes specific risk.

Results are summarized in the following table.

Table 1: Accounting Beta and Total Beta

This comparison analysis shows that accounting beta – net income has the lower average difference in absolute value (0,37). Differently from Intrisano, Palomba, Di Nallo, Calce (2017) where the measure with a lower value is ROE (with an absolute value of 0,17).

Another level of analysis is about the study of the sign of the difference between accounting beta and total beta in order to identify any trend.

Table 3: trend of differences between Accounting Beta and Total Beta

	Accounting Beta ROE – Total Beta	Accounting Beta Net Income – Total Beta	Accounting Beta Operating Income – Total Beta
Positive difference	1%	11%	13%
Negative difference	99%	89%	87%

Table shows that in most case the difference is negative. This means that very often total beta is higher than accounting beta. If we consider accounting beta ROE, we see that 99% of companies have total beta higher than

accounting beta. All the results confirm average value. In fact table about comparisons highlight that all the accounting betas have a negative average value (ROE -0,79; Net Income -0,37; Operating Income -0,59) and this is confirmed by the last table.

5. Conclusions

From literature review, we find that there are not model specially designed for unlisted companies. On one hand we have accounting beta model that it can be used for unlisted companies because it does not require price information, on the other hand we have total beta that also considers specific risk, that is characteristic in investors of unlisted companies. So the aim of the paper is to investigate relationship among accounting beta and total beta.

Accounting beta model seems to replicate better CAPM beta than total beta. This is confirmed by results about differences between total beta/CAPM beta and accounting beta. In fact in Intrisano, Palomba, Di Nallo, Calce (2017) accounting beta – ROE shows an average difference respect to CAPM beta equal to -0,17, while in this study the lower difference is done by accounting beta – Net Income (respect to total beta) with a value of -0,37. This represents a better performance of accounting beta-CAPM beta. Also the analysis about the sign confirm these findings. In our analysis we find that in most cases accounting beta leads to an underestimation respect to total beta, while in Intrisano, Palomba, Di Nallo, Calce (2017) we have heterogeneous results that imply an higher stability.

So accounting beta model is more suitable as control method for CAPM beta than a method thought for unlisted companies because results show a better stability for CAPM beta.

Ascertained that accounting beta seems to replicate better CAPM beta than total beta, concerning the question “Which accounting measure is the best?” in this paper we find a difference with Intrisano, Palomba, Di Nallo, Calce (2017). In fact in the previous work the best measure is represented by ROE, instead now the best measure is net income. The results show that the three accounting beta (ROE, net income and operating income) have different characteristic. Particularly net income has an average difference respect to total beta equal to -0,37, operating income -0,59, ROE -0,79. ROE now is the worst measure useful to reply total beta.

Definitely accounting beta does not seem useful to repeat total beta, moreover this model demonstrates some critical issues already cited in Intrisano, Palomba, Di Nallo, Calce (2017): accounting measures are often influenced by budgetary policies; they need of a greater number of observations, in fact we use 10 observations, because increasing the observations number we have the problem of considering a time horizon that is too long. This can lead to a not right valuation. One solution is represented by the use of quarterly accounting measure, but often this information are not available for all companies. Further levels of future analysis could be represented by the reply of this study on USA market, in order to investigate if different markets have same characteristics. In addition to this, also a systematic study about the relation between fundamental beta, the other significant approach, and total beta could represent a central theme.
